PRODUCT DESCRIPTION

The UT28F64LV amorphous silicon anti-fuse PROM is a high performance, asynchronous, radiation-hardened, 8K x 8 programmable memory device. The UT28F64LV PROM features fully asynchronous operation requiring no external clocks or timing strobes. An advanced radiation-hardened twin-well CMOS process technology is used to implement the UT28F64LV. The combination of radiation-hardness, fast access time, and low power consumption make the UT28F64LV ideal for high speed systems designed for operation in radiation environments.

DEVICE OPERATION

The UT28F64LV has three control inputs: Chip Enable (\overline{CE}), Program Enable (\overline{PE}), and Output Enable (\overline{OE}); thirteen address inputs, A(12:0); and eight bidirectional data lines, DQ(7:0). \overline{CE} is the device enable input that controls chip selection, active, and standby modes. Asserting \overline{CE} causes I_{DD} to rise to its active value and decodes the thirteen address inputs to select one of 8,192 words in the memory. \overline{PE} controls program and read operations. During a read cycle, \overline{OE} must be asserted to enable the outputs.

4. Functional test.

5. Derates at 1.5mA/MHz.

READ CYCLE

A combination of \overline{PE} greater than $V_{IH}(\min)$, and \overline{CE} less than $V_{IL}(\max)$ defines a read cycle. Read access time is measured from the latter of device enable, output enable, or valid address to valid data output.

An address access read is initiated by a change in address inputs while the chip is enabled with \overline{OE} asserted and \overline{PE} deasserted. Valid data appears on data output, DQ(7:0), after the specified t_{AVQV} is satisfied. Outputs remain active throughout the entire cycle. As long as device enable and output enable are active, the address inputs may change at a rate equal to the minimum read cycle time.

The chip enable-controlled access is initiated by \overline{CE} going active while \overline{OE} remains asserted, \overline{PE} remains deasserted, and the addresses remain stable for the entire cycle. After the specified t_{ELQV} is satisfied, the eight-bit word addressed by A(12:0) appears at the data outputs DQ(7:0).

Output enable-controlled access is initiated by \overline{OE} going active while \overline{CE} is asserted, \overline{PE} is deasserted, and the addresses are stable. Read access time is t_{GLQV} unless t_{AVQV} or t_{ELQV} have not been satisfied.

RADIATION HARDNESS

The UT28F64LV PROM incorporates special design and layout features which allow operation in high-level radiation environments. UPMC has developed special low-temperature processing techniques designed to enhance the total-dose radiation hardness of both the gate oxide and the field oxide while

maintaining the circuit density and reliability. For transient radiation hardness and latchup immunity, UPMC builds all radiation-hardened products on epitaxial wafers using an advanced twin-tub CMOS process. In addition, UPMC pays special attention to power and ground distribution during the design phase, minimizing dose-rate upset caused by rail collapse.
